2 Supplementary Methods

3 Location estimation from light-level loggers

4 Estimated timings of sunrise and sunset (twilight transition times) were computed from light data using 5 TransEdit2 (British Antarctic Survey/BAS, Cambridge, UK), and the twilightCalc function (GeoLight 6 package; Lisovski & Hahn 2012) in R 3.3.3 (R Development Core Team 2017) for BAS, Migrate Technology 7 and Biotrack loggers. Transition times were visually inspected for loggers retrieved during 2014-2017 by 8 the same person. Lotek loggers did not retain raw light intensity data, but rather calculated and recorded 9 latitudes and longitudes based on an on-board algorithm which has been shown to be biased 10 (Frederiksen et al. 2016). Therefore we used these threshold method (Lisovski & Hahn 2012) derived 11 positions to back calculate transition times using the lotek to dataframe function (probGLS 12 package; Merkel et al. 2016). Daily experienced sea surface temperature (SST) was estimated from raw 13 logged temperature data using the sst deduction function (probGLS package) with a possible range of -2 to 20°C for Lotek loggers and -2 to 40°C for all other brands. 14 15 A most probable track for each individual and tracking year was calculated using an iterative method utilizing probability sampling detailed in Merkel et al. (2016) and implemented in the 16 17 prob algorithm function (probGLS package). Input data were logger recorded transition times,

18 salt water immersion data as well as calculated daily recorded SST data. Daily optimal interpolated high

19 resolution satellite derived SST, SST uncertainty estimates and sea ice concentration data for the

algorithm with a 0.25° resolution were provided by NOAA (Boulder, Colorado, US; Reynolds et al. 2007).

21 To improve precision we included land avoidance, an inability to enter the Baltic Sea (except for

22 Common guillemots from the Isle of May) and an evasion of heavy pack ice (>90% sea ice concentration).

23 Each movement path incorporated parameters based on the ecology of the species and the

24 oceanographic conditions in the North Atlantic (table S1.1). Usually, it is not possible to estimate latitude

25 during times of equinox as day length (the proxy for latitude) is very similar everywhere on earth.

26 However, this methodology is able to estimate locations also during times of equinox by among other

27 things utilizing the recorded temperature data and comparing them to satellite derived sea surface

temperature (SST) fields. Due to small north-south gradients in SST in certain areas of the North Atlantic

29 (e.g. the Gulf Stream along the Norwegian coast) we limited the boundary box parameter in

- 30 prob algorithm for certain individuals and colonies after initial assessment of their movement track
- 31 (table S1.1). Each computed track was afterwards visually inspected and erroneous locations particularly
- 32 around polar night and midnight sun were removed (<1 % of all locations).

33 Environmental parameters

All chosen environmental parameters used to calculate the environmental space and their rational are listed in table S1.3. Fronts in sea surface temperature (SST) and sea surface height anomaly fields were calculated using a canny edge detector (package imager, low & high threshold at 90% & 98%, respectively). Bathymetry was log-transformed and all distance measurements were capped at 500 km as well as square root-transformed. Predictability in SST was calculated as the sum of constancy and contingency following Colwell (1974) over a ten year time period (2007-2016) with 10 equal bins using the hydrostats package (figure S1.1). All variables have been standardized (variance = 1, mean = 0).

41 Mantel correlation analysis

42 Following Cohen et al. (2018) we calculated species-specific Mantel correlations to validate our

- 43 migratory connectivity results with an independent method. All individual annual tracks were split into
- 44 10 day bins starting 1 July. A resolution of 10 days was chosen to retain a sufficient number of locations
- 45 for each bin for further analysis. Migratory connectivity for each species was quantified using Mantel
- 46 correlation tests with 1000 permutations (Ambrosini et al. 2009). More specifically, the distance
- 47 between individual breeding locations was compared to the distance between their current locations
- throughout the non-breeding season for each 10 day bin (as central location in each 10 day bin). For this
- 49 analysis only data from the last three years of tracking was used (2014/15 2016/17) due to the uneven
- 50 sampling across colonies in earlier years. To avoid pseudo-replication only one year of tracking for each
- 51 repeat track individual was used (randomly chosen). Further, ecoregion- and season-specific Mantel
- 52 correlation tests were computed for ecoregions with individuals from more than one population
- present during the focal time period to assess the area and season specific connectivity for each
- 54 species. Results are illustrated in figure S1.3.

108 Supplementary Tables and Figures

109

Table S1.1. probGLS algorithm input parameters used to compute locations. standard deviation = sd

algorithm parameter	algorithm parameter description			
particle.number	number of particles computed for each point cloud	2000		
iteration.number	number of track iterations	100		
loess.quartile	remove outliers in transition times based on local polynomial regression fitting processes (Lisovski & Hahn 2012)	used with k = 10		
sunrise.sd & sunset.sd	shape, scale and delay values describing the assumed uncertainty structure for each twilight event following a log normal distribution	2.49/ 0.94/ 0 ¹		
range.solar	range of solar angles used	-7° to -1° (except for C250 logger from SK: -4° to -2°)		
boundary.box	the range of longitudes and latitudes likely to be used by tracked individuals	90°W to 120°E & 40°N to 81°N; except for 91% COGU tracks from IM with 40°N to 62°N; all COGU from BI and 94% COGU SK tracks with 60°N to 77°N; 6% SK tracks with 50°N to 77°N		
day.around.spring.equinox لا days.around.fall.equinox	number of days before and after an equinox event in which a random latitude will be assigned	spring: 21 days before & 14 days after autumn: 14 days before & 21 days after		
speed.dry	fastest most likely speed, speed sd and maximum speed allowed when the logger is not submerged in sea water	17/ 4/ 30 m/s ²		
speed.wet	fastest most likely speed, speed sd and maximum speed allowed when the logger is submerged in sea water	1/ 1.3/ 5 m/s ³		
sst.sd	logger-derived sea surface temperature (SST) sd	0.5°C ⁴		
max.sst.diff	maximum tolerance in SST variation	3°C		
east.west.comp	compute longitudinal movement compensation for each set of twilight events (Biotrack 2013)	used		

111

¹These parameters are chosen as they resemble the twilight error structure of open habitat species in Lisovski et al. (2012).

² inferred from GPS tracks (unpublished data) and (Elliott & Gaston 2005)

³ North Atlantic current speed up to fast current speeds (i.e. East Greenland current) (Lumpkin & Johnson 2013) as the tagged animal is assumed to not actively move when the logger is immerged in seawater

116 ⁴ logger temperature accuracy

117 **Table S1.2.** Proportion of locations missing in each season mainly due to lack of twilight events caused by

118 midnight sun (seasons: autumn and spring) or polar night (early and late winter) for each breeding

119 population as well as mean and standard deviation (sd) across populations. Breeding populations: SNZ =

120 Southern Novaya Zemlya, NNZ = Northern Novaya Zemlya, ESP = Eastern Spitsbergen, WSP = Western

Figure S1.4. A schematic detailing the environmental similarity index (S) calculations in equation 1
(within example populations, solid lines) and equation 2 (between two example populations, dashed

156 lines) using two example populations (in black and grey). The symbols denote ecoregion-, species- and

157 breeding population-specific environmental space use. Its size corresponds to the proportional use as

visualised in figure 1B. Lines connect environmental spaces which are similar based on the

environmental niche similarity test (one way is considered sufficient, i.e. $niche 1 \cong niche 2 \mid niche 2 \cong$

160 niche 1).

Figure S1.6. Seasonal proportional comparative space and environmental niche use between both species breeding sympatric at four breeding locations (JM = Jan Mayen, IC = North-East Iceland, BI = Bjørnøya & SBS = Southern Barents Sea). The proportion of the population occupying the same ecoregion with the other sympatric species breeding at the same location is indicated in white-grey-black colours while red-orange colours indicate different ecoregions used. Dark colours (grey & black) correspond to speciesspecific within ecoregion space use while white illustrates mixing between the species within ecoregions. Solid colours (white, grey & red) indicate similar environmental niches occupied while shaded colours denote distinct environments used (black & orange).
