

## Supplementary material

### **Text S1. Protocol used to extract the MPB from the sampled sediments.**

To extract the MPB from the sediment, we used liquid silica (LUDOX HS-30). The sampled sediment was defrosted in a refrigerator, then 5 ml of homogenized sediment was placed into a 50 mL falcon (A) and 25 mL of LUDOX HS-30 were added. The falcon tubes were then mixed, placed into an ultrasound bath for 15 min and mixed again. After, they were centrifuged at 5000 rpm for 15 min at 10°C and the supernatant containing the MPB was placed into another falcon using a clean pipet (B). All the steps between A and B were repeated three times for each 50 ml falcon tube. In the end we had a new falcon tube containing a mix of MPB and liquid silica that we rinsed using MilliQ water and the dilution 3 MilliQ water for 1 supernatant. The falcon containing the supernatant and the MilliQ water was centrifuged at 3500 rpm for 10 min at 10°C, the resultant supernatant was removed and the rest was placed at -80°C until further processing.

**Table S1.** Carbon and nitrogen isotope ratios ( $\delta^{13}\text{C}$  and  $\delta^{15}\text{N}$ ), with the corresponding standard deviations (SD), of the different macroinvertebrate and vertebrate species sampled in the control, associated and engineered sediments in winter and summer. The relative biomass contribution of each species to the total biomass sampled in each sediment is indicated as % biom and the species accounting for more than 1% of the total biomass are in bold. The vertebrate species indicated in the engineered sediment section were sampled in the reef zone and were represented on the engineered and associated sediment isotopic biplots (Fig. 1). Some species were only sampled in the cores used for the isotopic analysis and not in the ones used for the biomass estimations. Hence, we could not estimate their biomass which is indicated by (-).

**Table S2.** Estimated contributions of the two (control site) or three (Reef site) main food sources, particulate organic matter (POM), microphytobenthos (MPB) and green algae from the genus *Ulva* (ULV), for the primary consumers present in the control, associated (AS) and engineered (ES) sediments in winter (W) and summer (S) using the Stable Isotope Mixing Model in R (simmr). The mean contribution  $\pm$  the standard deviation of the mean contribution followed by the 97.5% confidence interval are indicated. The sum of the pelagic (POM) and benthic (MPB for the control site and MPB + ULV for the reef site) mean contributions is also indicated. The mixing model was run for species for which we had at least three replicate samples by sediment type and season, identified as n in the table. The species accounting for more than 1% of the total biomass in each sediment type (Sed) in winter and/or summer are designated by \* for the CS and AS and # for the ES.

Control site					Reef site
