

Supplementary Information

Supplementary Table S1. The top 20 tested POPAN models and their respective selection metrics. . The final model used for inference had the lowest AICc value. Candidate models considered different covariate relationships with apparent survival probability (Phi), detection probability (p), and entry probability (pent), and either equal superpopulation size (N) between males and females (~1) or sex specific superpopulation sizes.

Model Formula	AICc	ΔAICc	AICc Weight	Deviance

Supplementary Table S2. Parameters of the top four POPAN models and their resulting superpopulation size. All four models accounted for 73.9% of the AICc weight. In parentheses, AICc weight is reported in bold in the top row, while remaining rows include the confidence intervals in parentheses.

Supplementary Figure S1. Comparison of parameter estimates from the top four mark-resight models. a) Apparent survival estimates by year. b) Entry probability estimates by year. c) Sighting probability estimates by year. d) Superpopulation size estimates by sex. See results for model specifications. Vertical lines represent standard errors. We note that while standard errors were low for many entry probability estimates, the full confidence intervals spanned 0-1 in many cases (see Supplementary Table S2).
